A COOPERATIVE VEHICULAR IDENTIFICATION SYSTEM

(A Vision of Utility and Civility for Roads and Highways)

Cross-Reference to Related Application

This application claims the benefit of provisional Application No. 60/364,303, filed March 14, 2002, entitled *A Cooperative Vehicular Identification System*, assigned to the assignee of the present application, the disclosure of which is hereby incorporated herein by reference in its entirety as if set forth fully herein.

Description

Cooperative Vehicular Identification Systems and Methods, capable of monitoring and recording vehicular law violations, with the assistance and cooperation of the vehicles in violation, are disclosed. In accordance with some embodiments of the invention, real-time information from vehicular sensors is communicated to a Central Processing Unit (CPU). Strategically located Interrogator devices, on roads/highways, at intersections, in and around school zones, integrated with traffic lights, etc., issue inquiries/interrogations to passing-by vehicles. Vehicles proximate to such Interrogators respond with unique identifying information and with parameter lists provided by their vehicular sensors. In some embodiments, each Interrogator inquiry provides data, including the lawful parameter limits (i.e. speed limit) associated with its location. In response to having successfully decoded an inquiry, and in response to the state of its vehicular sensors, a vehicular Transponder may transmit information to the specific Interrogator that has issued an inquiry. The Interrogator then relays relevant identifying information to the CPU for further processing.

Cooperative Vehicular Identification Systems and Methods according to some embodiments of the invention, hereinafter referred to as CVIS, may also provide a

public service to motorists by delivering real-time road-specific reports relating to traffic, accidents, weather conditions, etc. In other embodiments, CVIS may further provide a service to motorists by delivering store-and-forward messages (e-mail) to and from their vehicles. In other embodiments, CVIS may also serve as a "mobile yellow pages" providing selective, area-specific information relevant to leisure, shopping, and/or entertainment activities, in response to motorist initiated inquiries. Some embodiments may also provide distress assistance to motorists. Toll collections may be handled very effectively, and some embodiments may even be configured to tell you where to find a parking spot as you approach a parking area.

10

CVIS can pay for itself very quickly with the dollars of vehicular law violators. Significant new revenue may be generated for State and Local authorities since many or every violator can be apprehended electronically. CVIS may derive additional revenues from services provided to commerce and/or individuals, or may chose to offer (at least some) of its services free of charge as a public service to the community.

Significant business potential exists for industry that may engage in the development, manufacturing, deployment, maintenance, and upgrades to CVIS. In the United States alone, more than 15 Million (lightweight) new cars are sold each year, and there are more than 200 Million such vehicles already in operation. There are also more than 40 Million fleet vehicles US-wide. For all of these vehicles to be CVIS compliant, according to some embodiments of the invention, each one may be equipped with a Transponder. The number of Interrogators that could be deployed US-wide could exceed tens of thousands.

Following the successful deployment of CVIS in the United States, deployment in other countries may follow.

30 Besides detecting violations such as speeding, some embodiments of CVIS will also be able to detect events such as not having stopped at a red light and/or a stop sign, and will be able to search, locate, and track a vehicle, in response to law enforcement commands, throughout a city and/or throughout the entire country.

1. INTRODUCTION AND SUMMARY

Embodiments of CVIS described hereinbelow can potentially benefit society in significant ways. Some embodiments of CVIS may:

5

- (1) Save lives (many lives).
- (2) Reduce significantly the number of vehicular accidents, minor and major, and the associated injuries, suffering, and expense/loss in productivity.
- (3) Stabilize and even reduce car insurance premiums (as a consequence of (1) & 10 (2) above).
- (4) Instill a heightened awareness of lawful driving behavior to the public at-large (thus re-enforcing (1) through (3) above).
- (5) Be a strong anti-theft deterrent.
- (6) Offer emergency/distress assistance to motorists.
- 15 (7) Offer real-time, road-specific, information to motorists as well as other more general information, for leisure and recreational activities, including personal messaging.

A focus of CVIS is on strengthening vehicular law enforcement and mitigating 20 irresponsible driving behavior, thus improving safety for pedestrians and drivers alike. Deployment of CVIS can make vehicular law enforcement automatic, efficient, non-discriminatory, quick, non-intrusive, and/or transparent to the violator and law enforcement agency alike. While being an instrument of beneficial social engineering, embodiments of CVIS also can generate significant new revenues for state/county 25 law-enforcement agencies and can thus pay for itself with the dollars of those who violate the Law. Embodiments of CVIS may thus be envisioned as a selective tax imposed only on vehicular law violators. Other embodiments of CVIS, however, may also generate revenue by delivering area-specific commercial, leisure, and/or recreational information to motorists' vehicles. That is, some embodiments of CVIS 30 can be a "mobile yellow pages" for restaurants, cinemas, stores/malls, promotions, etc, as well as a system for delivering store-and-forward personal messages and/or e-mail to people in transit.

To those who will criticize CVIS as being a "Big Brother is Watching" type of a system, we offer this simple response: Driving on public roads and highways is a necessity of modern life, and is an activity conducted daily by an overwhelming majority of the adult population. Driving on public roads and highways, therefore, is

5 an activity that impacts almost all people daily, either directly or indirectly. Because of its broad reaching affects on society, driving must be conducted responsibly and within the guidelines set forth by Law. According to some embodiments of CVIS, while a driver's activities remain lawful, "Big Brother" is blind. Only when a motorist's actions violate the Law, only then do Big Brother's eyes open to take

10 notice.

We have all witnessed the reckless driver who routinely violates the posted speed limit. We have repeatedly witnessed the careless driver who goes through stop signs without first making a complete stop. We have even seen those who go through red lights in their eagerness to get to their destinations a few minutes earlier. Many drivers still do not wear seat belts and many more execute turns without bothering to indicate their intentions. All these vehicular law violations, and many more, would be noticeable and recordable by some embodiments of CVIS. Each event associated with a violation would be recorded at a central processing unit and would also be tagged

15 with the registered identity of the vehicle involved, the time-of-day of occurrence, and position coordinates of occurrence.

20

2. ELEMENTS

- 25 The present invention now will be described more fully hereinafter with reference to the accompanying figures, in which embodiments of the invention are shown. This invention may, however, be embodied in many alternate forms and should not be construed as limited to the embodiments set forth herein.
- 30 Accordingly, while the invention is susceptible to various modifications and alternative forms, specific embodiments thereof are shown by way of example in the drawings and will herein be described in detail. It should be understood, however, that there is no intent to limit the invention to the particular forms disclosed, but on

the contrary, the invention is to cover all modifications, equivalents, and alternatives falling within the spirit and scope of the invention as defined by the claims.

An element of some embodiments of CVIS is the Transponder-Interrogator pair of
5 Figure 1. The Transponder resides in a vehicle and can thus be classified as a mobile device. The Interrogator may (or may not) reside in a vehicle and thus may (or may not) be a mobile device. Interrogators may be installed in law-enforcement vehicles (police and/or state trooper vehicles) but, in other embodiments, Interrogators may be installed in fixed locations, perhaps on top of light poles and traffic signs (on the sides
10 of roads and highways), integrated with traffic lights at road intersections, situated close to stop signs, strategically located in and around school zones, and in many other places where vehicular law enforcement is of importance and concern.

As is illustrated in Figure 1, an in-vehicle Transponder receives inputs from a
15 plurality of vehicular sensors (via physical electromechanical connections and/or wirelessly). Inputs to the Transponder may be speed of the vehicle, left- and right-turn signal states, odometer reading, GPS receiver data, vehicular theft sensor indications, driver's seat belt state (on/off), etc... Inputs to the Transponder may also arrive (wirelessly or otherwise) from a man-machine interface that may be used to pre-
20 condition the Transponder to request certain information when in the proximity of certain Interrogators.¹ Permanently stored within a non-volatile memory of each Transponder, will be a unique identifier (ID) of the vehicle associated with that Transponder.

25 An Interrogator, as shown in Figure 1, transmits and receives information to and from the Transponder. In addition, the Interrogator relays information to a centrally located processing unit (computing center) and is also capable of receiving information (from said processing unit and/or other sources). In some embodiments, the Interrogator transmits information to the Central Processing Unit (CPU) and receives information
30 from the CPU or said other sources, in substantially real time, using, for example, a

¹ The Transponder may request local-area commercial information such as, for example, the three closest (relative to its location) restaurants offering French cuisine, or the two closest cinemas with a current list of movies playing, etc. Such information may be provided as a public service to motorists by the Local/State transportation authorities over their corresponding Interrogator networks. The

GSM packet-data protocol such as GPRS (or EDGE). Terrestrial cellular/PCS or satellite-based data/paging networks can be used to connect the Interrogator to its designated CPU². Dedicated line-of-sight microwave links or other media such as wire or fiber-optical cable may also be used. See, for example, Figure 10.

5

3. MONITORING OF VEHICULAR PARAMETERS

Two groups of embodiments that can be used to detect violations of vehicular law are described below. Following a reading of this section, it will be apparent to one of ordinary skill in the art that a number of combinations and variations on the embodiments discussed hereinbelow are possible. Even though this is recognized, we do not attempt to be exhaustive; rather, we chose to be comprehensive and thorough, focusing on two specific embodiments, so that the scope and spirit of the disclosure can be conveyed fully and unambiguously to one of ordinary skill in the art.

15

3.1 First Embodiments - The Independent Interrogator

In accordance with first embodiments (the independent Interrogator concept) Interrogators are positioned at predetermined locations, along the sides of highways and roads, and are configured to transmit an interrogation periodically, say once every 0.5 seconds.³ Vehicle Transponders proximate to such Interrogators (i.e. within listening range) may be triggered to provide a response. Even when an interrogation is reliably received (error free) by a vehicle Transponder, said vehicle Transponder may or may-not be triggered to respond. In some embodiments, the decision to respond may depend on the type of interrogation message received, requesting a conditional or an unconditional response. In other embodiments, the decision of a Transponder to respond may also depend on whether or not said Transponder has already responded

service can be free of charge to the commercial entities being promoted, or a nominal monthly fee may be charged.

² A US-wide paging network may be used to provide urban and suburban connectivity between the plurality of Interrogators and their corresponding CPUs. Non-time-critical updates of Interrogators by the CPU and the transferring of non-time-critical data to the CPU from the field devices (Interrogators) may take place during off-peak hours of the day and night. In some embodiments, only time-critical updates should be scheduled to occur in substantially real time.

³ In some embodiments, independent Interrogators of the type described in this section may also be installed in law-enforcement vehicles.

to the particular Interrogator, within a predetermined elapsed time interval. By suppressing subsequent Transponder responses to the same Interrogator (over a predetermined time interval) some embodiments of the invention may eliminate many redundant Transponder responses (that otherwise may be transmitted) thus reducing
5 the probability of response collisions.

As has already been noted, an interrogation may request a conditional or an unconditional Transponder response. Subject to the conditional interrogation, the Transponder will respond if it is in violation of some aspect of the Law. For example,
10 if the driver is not wearing his/her seat belt, and/or if the vehicle has not passed inspection within the time limit allowed, and/or if the speed limit is being violated. Furthermore, if the vehicle has been subjected to unauthorized usage (has been stolen, as determined by the vehicular sensors), and/or if the vehicle has been reported stolen,⁴ a Transponder response will also be issued.
15

In some embodiments, each interrogation, whether it is of the conditional or unconditional type, relays a unique Interrogator identifier (ID), a measure of the physical coordinates of the Interrogator, the Time of Day (ToD), the lawful speed limit, and may also relay additional broadcast information that may be relevant to
20 motorists proximate to the Interrogator site. Figure 2 shows additional illustrative detail regarding an interrogation packet structure according to some embodiments of the invention. The Transponder reads the data contents of the interrogation, correlates said data (e.g. speed limit) with the actual data (e.g. speed of the vehicle as provided to the Transponder by the vehicular sensors; see Figure 1) and decides whether a
25 response to the received interrogation is warranted. A response to the received interrogation may be initiated based on either unacceptable (unlawful) vehicular sensor states and/or any other violation-of-the-law, or it may be based on some other condition such as the need for commercial information or a personal message to be delivered.

30

⁴ How the vehicle knows that it has been stolen (other than detecting unauthorized usage with its own sensors) will be discussed later.

In some embodiments, should the Transponder decide to respond, the response will include the vehicle's unique identification number, the ToD, position coordinates, the lawful speed limit (as relayed to the Transponder by the Interrogator); the vehicle's actual speed, red light & stop sign flag status (the significance of which will be discussed in detail later); the driver's seat belt status (ON/OFF); inspection status; theft status; and/or driver's distress status (see Figure 3). The Transponder response may also contain an inquiry requesting from the Interrogator certain local-area information. The Transponder response may also indicate the presence of a message to be delivered (from the vehicle to some destination; see Figure 3). The driver's distress status, when activated (either manually or by voice command) will serve to automatically notify the authorities that the vehicle is in distress. The authorities will be able to identify the distressed vehicle's location by the unique ID and position coordinates of the Interrogator relaying the distress message to the CPU. From that point on, some embodiments of CVIS could track the vehicle as it encounters successive Interrogator sites. There could even be specially marked areas, on the sides of roads and highways, equipped with Interrogators that include, for example, Bluetooth-based and/or other wireless audio/video means. Such Interrogators, when triggered by a vehicle's distress message could offer audio/video connectivity between said vehicle and the authorities. The Transponder may also be equipped with the appropriate audio/video interface.⁵

In other embodiments, if a Transponder decides to send a response to an interrogation because there is some aspect of the law that has been violated, the response will also be stored locally within the Transponder. In addition to keeping a local copy of its response, the Transponder may also store a digital image and/or other characteristic of the driver.⁶ Given that the Transponder's response is received reliably by the Interrogator (as determined, for example, by a CRC field and/or other error checking) the Interrogator will copy said Transponder response in memory and will send a confirmation to the issuing Transponder (see Figure 4). The Transponder, upon receipt of the confirmation, will store the data contents of its confirmed response in

⁵ The vehicle in distress also may need to pull over into such a specially marked area and stop in the proximity of the Interrogator to establish connectivity.

- non-volatile memory as a “permanent record” of the violation event. All parameters in violation will be stored, together with the time-of-day, lawful speed limit, and position coordinates associated with the violation (the position coordinates associated with the violation, the time-of-day, and the lawful speed limit are those relayed to the
- 5 Transponder by the Interrogator). As part of this permanent record, the digital image and/or said other characteristic of the driver will also be stored. From this time on, in some embodiments, the Transponder may ignore all subsequent interrogations that may be received from the same Interrogator over a predetermined time interval.
- 10 In other embodiments, in the case of an unconditional interrogation, the vehicle is obliged to respond whether it is in violation of the law or not. No permanent record is kept by the Transponder (per the above discussion) unless the vehicle happens to be in violation of some aspect of the law. This mode of Transponder response, to the unconditional interrogation, may be used in places where the authorities desire to
- 15 gather statistics on parameters such as the number of vehicles passing by a particular location at different times of the day, the distribution of speed at that location, the types of vehicles (private cars, taxis, trucks, etc.) passing by that location, etc... As with the Transponder response to a conditional interrogation, here too, a confirmation by the Interrogator is sent to each responding Transponder in some embodiments.
- 20 This may be done to silence the Transponder from responding to subsequent interrogations that may be received from the same Interrogator over a predetermined time interval.

25 **3.2 The Concept of Notifiers - Second Embodiments - The Dependent Interrogator**

In accordance with second embodiments of the invention, the Interrogator does not transmit unless it is triggered by a near-by Transponder whose associated vehicle is in violation of some aspect of the law, or in distress, or needs to receive or transmit

30 information. Some embodiments, may work as follows: Each road containing Interrogators also contains other devices referred to as Notifiers. A Notifier is a

⁶ Means of generating such an image may be provided as part of the overall Transponder instrumentation. Other means such as those that would “sniff” the in-vehicle air for alcohol content may also be provided.

transmit-only device that relays information to near-by (passing-by) vehicles. The Notifier does not receive information from vehicles, only transmits to them. In some embodiments, the Notifier, however, can be configured to communicate bi-directionally with the CPU. The Notifier will periodically transmit its coordinates,

- 5 ToD, and the lawful (posted) speed limit for its location, and may also be enabled to transmit other information such as road conditions, traffic reports, accident reports, weather bulletins, etc. In other embodiments, the Notifier may also be configured to transmit a "you have been stolen" message which would be aimed at specific vehicles that have been reported stolen.⁷

10

We return now to describe how Interrogators may be triggered to interrogate in accordance with some embodiments of the invention. When a Transponder has received information from a Notifier and said Transponder decides that, based on the received information, it is engaged in some unlawful activity, the Transponder

- 15 begins to periodically broadcast a message. The Transponder broadcasts (at say frequency f_i) its unique vehicle ID and the Notifier's coordinates, pseudo-randomly changing the carrier frequency f_i from broadcast to broadcast. The Transponder broadcasts and then listens; broadcasts and then listens; in a time division duplex fashion, both broadcasting and listening at f_i . Each Interrogator listens to all possible
20 Transponder broadcast frequencies f_i ($i = 1, 2, \dots, L-1, L$). Hence, when an Interrogator hears a Transponder's broadcast, the Interrogator responds by interrogating the specific Transponder whose broadcast it has just heard. The interrogation is transmitted at carrier frequency f_i , while the Transponder is still listening at f_i .

25

Embodiments of an Interrogator packet format are illustrated in Figure 2. Embodiments of the Transponder response are illustrated in Figure 3. Embodiments of the confirmation by the Interrogator to the Transponder are shown in Figure 4. In some embodiments, all this exchange occurs at the same frequency f_i ; the frequency at

⁷ Imagine a very sophisticated thief who manages to steal a vehicle without triggering any of the unauthorized use (theft) sensors of the vehicle. When the owner of said stolen vehicle becomes aware of the fact and notifies the authorities, the authorities can command all Notifiers in the area (via the CPU) to start transmitting the "you have been stolen" message, accompanied by the stolen vehicle's unique ID. When the stolen vehicle's Transponder receives the notification, it will identify itself as stolen at the next Interrogator site (together with position coordinates) thus notifying the authorities of its whereabouts.

which the Interrogator was triggered by the Transponder to interrogate. This, however, need not be the case. For example, the Interrogator, having been triggered to interrogate at f_i , could include in its interrogation a command instructing the Transponder to reply at f_j ($f_i \neq f_j$). Alternatively, the Interrogator can be told, via the broadcast message that triggers it, to interrogate at f_k ($f_k \neq f_i \neq f_j$) etc. When the above exchange of information between Transponder and Interrogator is complete (as indicated by the confirmation to the Transponder by the Interrogator) the Transponder ceases all further transmissions of its broadcast until it is once again triggered by some other Notifier. In some embodiments, the Transponder broadcasts will not cease, however, if they are caused by a vehicle theft condition. If the Transponder's broadcasts relate to a stolen vehicle state, the broadcasts will continue to facilitate vehicle tracking as said vehicle travels from Interrogator site to Interrogator site.

According to some embodiments, one reason for including the Notifier's coordinates in the Transponder's broadcast message, is to reduce or preclude the possibility of having vehicles wrongly accused of violating the speed limit. One can imagine, for example, a vehicle on a highway violating the speed limit by going 75 mph while the posted speed limit is 55 mph. Let's assume that said vehicle is broadcasting, and imagine a location where the highway and a city road come very close together. Furthermore, let's assume that, due to an engineering oversight or other reason, an Interrogator situated on the city road (at the point where the city road and the highway come close to each other) can hear broadcasts of vehicle Transponders traveling on the highway. By deciphering the broadcast message, and reading the Notifier's coordinates, the road Interrogator can ignore all highway vehicle broadcasts (even though some aspect of the law has been violated) since the Notifier's coordinates make it clear that said broadcasts relate to vehicles on an other road/highway and, hence, will be handled by Interrogators on said other road/highway. Similarly, if due to some improper installation/calibration of a Notifier or other reason, its radiated signals are heard by Transponders on roads/highways other than the intended one, Interrogators on said "other than the intended one" route will ignore any broadcasts initiated by said Transponders. Failure to correlate between the Notifier's "coordinates", as relayed by the Transponder's

broadcast, and those of the listening Interrogator, can inhibit triggering the Interrogator to interrogate⁸.

In some embodiments, Notifiers frequency-hop from one notification message to
5 the next in order to comply with regulatory requirements of the unlicensed-frequency
Instrumentation, Scientific and Medical (ISM) band. Each notification message is
repeated at each transponder listening frequency f_i ; $i = 1, 2, \dots, L$. Preferably, the L
repeats of each notification should occur over a short period of time (e.g., within 500
ms or less). In some embodiments, transponders do not have any timing or frequency-
10 hop pattern information relative to Notifiers. A Transponder simply tunes its
receiver to a frequency, randomly selected from the set $\{f_i; i = 1, 2, \dots, L\}$, and
listens. Figure 5a illustrates how the frame format for a Notifier packet may be
configured. As can be seen from the Figure, the notification packet relays ToD,
position coordinates, lawful speed limit information, as well as road conditions
15 information. The road conditions information may be anything that the authorities
deem important for motorists such as accident reports, congestion reports, slippery
road conditions, weather reports, etc... In addition to the above, the notification
packet may also contain stolen vehicle information. As shown on Figure 5a, up to J
stolen vehicle IDs may be broadcast. In some embodiments, what limits the value of J
20 is the constraint that within 500 msec (or so) the Notifier is able to repeat the
notification packet L times. Hence, when the stolen vehicles list exceeds the limits set
forth by the above requirement, a longer notification message may be created
spanning several hops. Each frequency-hopped notification message segment can
reveal the next hop frequency at which the message is to be continued (see Figure 5b)
25 so that the Transponder can follow the hopping pattern of the Notifier. Thus, the

⁸ It should be understood that the term "coordinates" is used throughout this document in a very liberal sense. In some embodiments, the term coordinates is not used with geometrical rigor to specify a precise point in space; rather, it is used to specify a particular road/highway and in some cases a specific location on said road/highway (e.g. route 495 between exits 50 and 51). It is envisaged that Notifiers and Interrogators belonging to the same road/highway will be positioned close to each other (may even be co-located, or even physically integrated onto one assembly). As such, the "coordinates" relayed by a Transponder broadcast should always correlate, at least with regard to the specified road/highway, with the coordinates of an Interrogator hearing the broadcast. In other embodiments, precise geometrical coordinates may be used.

Transponder may be able to read the entire stolen vehicles list.⁹ However, there is one additional issue regarding relatively long Notifier messages: The vehicle may need to be moving relatively slowly or be stationary in order to hear the entire message. If the vehicle is in relative fast motion, it may find itself out-of-range of the Notifier 5 before the entire message has been transmitted. This issue is the topic of the next section.

3.2.1 Special Purpose Notifiers at Stop Lights

- 10 Special Purpose Notifiers may be strategically positioned in the proximity of traffic lights. Such Notifiers may contain lists of reported stolen vehicles (as relayed to them by the CPU) and may broadcast such lists periodically. The placement of Notifiers in the proximity of traffic lights can offer advantages to the system. As a traffic light turns red, most vehicles (even those in the possession of thieves) stop.
- 15 The (relatively long) time interval over which vehicles remain stationary at traffic lights allows the Notifier to transmit a significantly longer stolen vehicles list than it could otherwise be able to. As a result, the probability that a stolen vehicle will hear the message "you have been stolen", as relayed to it, for example, via a broadcast of its unique vehicle ID, is increased. Once a stolen vehicle receives the notification that
- 20 it has been stolen, its "theft status" flag is raised, thus triggering the vehicle to start broadcasting, as already discussed, in accordance with the second embodiments.

The frame format configuration for this relatively long message may be as shown on Figure 5b. The entire message may include many segments similar to the one 25 illustrated on Figure 5b. Each message segment may be identical in form to the previous one but this is not necessary. For example, in some embodiments, the ToD and position coordinates may be omitted following the first message segment, but if a vehicle starts listening to the message after the first segment, that vehicle would be in the dark regarding ToD and position (unless of course it waited long-enough to hear 30 the beginning of the message). Another alternative embodiment may include ToD and position coordinates intermittently, say once every 10 message segments.

⁹ Alternative embodiments use a Direct Sequence, Spread-Spectrum Notifier mode, and a corresponding Transponder receiver demodulator, so that relatively long Notifier messages can be transmitted over a predetermined (non-frequency-hopped) channel.

At the beginning of the “stolen vehicles list” notification message and intermittently thereafter, the message segment may be repeated on all Transponder listening frequencies in order to get all proximate Transponders to track the message (to follow 5 the frequency-hopping pattern)¹⁰. By doing so, all Transponders in the vicinity of the Special Purpose Notifier can receive a message segment which reveals the value of the next hop frequency at which the message is to be continued.

4. TIME-FREQUENCY PLAN: First Embodiments

10

In some embodiments, an Interrogator sequentially transmits its interrogation on all possible frequencies (f_1 through f_L) that Transponders may be listening to. Figure 6 illustrates a time-frequency plan according to some embodiments. The entire 15 interrogation packet (as illustrated on Figure 2) is first transmitted on f_1 , followed by retransmission on f_2 , then on f_3 , and continuing on until the same interrogation packet has been transmitted on all Transponder listening frequencies. Each Transponder randomly selects a frequency to listen to from the a priori stored set $\{f_1 \text{ through } f_L\}$. When a Transponder receives the interrogation packet and decides to respond (either based on some violation of the law criterion, a distress state, or because the 20 interrogation is of the unconditional type, etc.) the Transponder randomly selects one out of the N available time slots (see Figure 6) within which to send its response. In some embodiments, N is a number between 16 and 32. Generally, the larger N is, the smaller the probability becomes that responses will collide. For example, assume 100 vehicles near an Interrogator, able to detect interrogations, and say that 10 of these are 25 in violation of the law. Furthermore, assume that the Transponders of these 100 vehicles are uniformly distributed over the listening frequency set. With N orthogonal time slots per listening frequency, the probability of a response collision is $10/LN$. With $L = 20$ and $N = 16$, the probability of a Transponder response collision becomes $(10/320) = 1/32$, for this example. Setting $N = 32$, makes the above probability 30 become $1/64$. In the event of a collision, the Interrogator will (most likely) not recognize any response (over the time slot where the collision occurred) and will,

¹⁰ As will be described later, when the Special Purpose Notifier is co-located with Traffic Light State Notifiers, this may not be necessary.

therefore, not transmit a confirmation. Thus, the Transponders involved in the collision will continue to respond to subsequent interrogations.

In some embodiments, all Transponder responses that are received error free by the
5 relevant Interrogator are acknowledged via a confirmation to the issuing Transponder.
As illustrated on Figure 6, there are four Transponder responses over frequency f_1 , on
time slots 1, 3, 6, and 7, respectively. Following the last interrogation repeat (at
frequency f_L) the Interrogator goes back to f_1 to acknowledge the four received
Transponder responses. Then, the Interrogator jumps to f_2 to acknowledge the six
10 Transponder responses there. Following f_2 , f_3 is served, and so-on, all the way down
to f_L . In serving acknowledgements on any one of the frequencies f_i ($1 \leq i \leq L$) the
Interrogator stays on f_i for a length of time equal to what would be needed if the
Interrogator had to serve N acknowledgements, even though less than N
acknowledgements will typically be required. After this length of time, the
15 Interrogator moves on to f_{i+1} to serve the acknowledgements there, and stays on f_{i+1}
for a length of time equal to the maximum that would be required for the Interrogator
to serve the maximum of N confirmations.¹¹ These embodiments can maintain
invariant time-line relationships between events occurring over the plurality of
frequencies f_1 through f_L . Other embodiments, however, are possible where the
20 Interrogator serves the acknowledgements at a given frequency immediately
following the received Transponder responds at that frequency. Following the last set
of acknowledgements at frequency f_L , the Interrogator returns to f_1 and the process
starts all over again with the Interrogator issuing its interrogation sequentially over the
entire frequency set¹².

25

Note that the frequencies f_1 , f_2 , ..., f_L need not represent contiguous values or values
that are monotonically increasing. Furthermore, the Time Division Duplex
Multiplexing (TDDM) approach, regarding the Interrogator/Transponder exchange, as

¹¹ The terms confirmation and acknowledgement are being used interchangeably.

¹² It may be desirable for the period of the process to be confined to 500 msec. In some embodiments, this can assure that even when traveling at relatively high speeds, vehicles will have ample time to hear and respond to interrogations. The 500 msec target can be met by a system whose over-the-air transmission rate is about 1 Mbps or more. Preliminary calculations regarding packet lengths indicate that the interrogation packet can be bounded by about 5,800 bits before Forward Error Coding (FEC) resulting in about a 10,000-bit packet after FEC is applied. The Transponder packet is bounded by about 810 bits (before FEC) resulting in about a 2,000-bit packet following FEC overhead.

discussed above and illustrated on Figure 6, may be replaced with a Code Division Multiplexing (CDM) methodology where instead of time, code orthogonality is relied upon to separate Transponder responses at the Interrogator receiver. Still further embodiments use Frequency Division Multiplexing (FDM) whereby frequency orthogonality is used in lieu of either TDDM or CDM. In addition to the above, other combinations and/or variations of multiplexing schemes as well as other time-frequency relationships that are within the scope and spirit of what has been disclosed hereinabove, will occur to those skilled in the art. For example, in accordance with the TDDM approach of Figure 6, instead of waiting for all Transponder responses (at a given f_i) to first arrive at the Interrogator before transmitting confirmations, embodiments whereby acknowledgements (confirmations) are transmitted by the Interrogator immediately following the receipt of a Transponder's response may be implemented.

15 **5. TIME-FREQUENCY PLAN: Second Embodiments**

As has been stated earlier, in accordance with the second embodiments, shortly after a Transponder is triggered by a Notifier to start broadcasting, said Transponder pseudo-randomly selects a frequency from the set $\{f_i; i = 1, 2, \dots, L\}$ and begins to transmit identifying information over said frequency. The Transponder broadcast burst is transmitted periodically (for example, once every 500 msec) until an Interrogator is triggered to interrogate. As illustrated in Figure 7, when an Interrogator is triggered, the Interrogator/Transponder exchange followed by the Interrogator confirmation takes place, at the end of which the Transponder's periodic broadcast sequence may end. Figure 7 illustrates a time lag between the Transponder broadcast that triggers the Interrogator and the interrogation itself. This is intended to illustrate that the Interrogator may be busy serving other broadcasts and/or is busy with other time-critical functions.

30 **6. TRANSPONDER OPTIONS FOR CHANGING TRANSMIT AND RECEIVE FREQUENCIES**

In accordance with the second embodiments, it has already been stated that the Transponder, once triggered to start broadcasting, pseudo-randomly (and in some

- embodiments, uniformly and with no bias over the available frequency set) changes transmit/receive frequency once per broadcast interval (at least once about every 500 msec). When the Transponder is not in the broadcast mode, it randomly (and in some embodiments uniformly) selects a frequency from the set $\{f_i; i = 1, 2, \dots, L\}$ to listen to. The Transponder stays at the chosen frequency, and continues to listen for Notifier messages until a Notifier message and some violation of the law and/or a distress state and/or the Transponder's desire to transmit or receive information, triggers said Transponder once again into the broadcast mode.
- 10 In accordance with the first embodiments, each Transponder can be configured so that in response to each received interrogation confirmation message the Transponder hops pseudo-randomly (and preferably uniformly) to a new frequency f_i . Consequently, even if all Transponders at the time of manufacturing and/or installation are initialized to a common receive/transmit frequency f_0 , $\exists: f_0 \in \{f_1, f_2, \dots, f_L\}$, offenders would soon be randomized. Alternative embodiments may entail assigning, in a pseudo-random fashion, at the time of manufacturing and/or installation, a receive/transmit frequency to each Transponder, which the Transponder then maintains ad infinitum. Variations of the two embodiments may also be used.
- 15

20 **7. THE TRAFFIC LIGHT NOTIFIER SET**

We have already described how embodiments of CVIS may be used to identify and record various driving violations such as exceeding of the speed limit, the driver not having engaged the seat belt mechanism, operating a vehicle with expired inspection 25 status, driving a stolen vehicle, etc. We have also described how embodiments of CVIS can serve as a safety net for drivers in distress and how embodiments of CVIS can provide other services and information to motorists. In this section, we describe other embodiments of CVIS - the ability of embodiments of CVIS to detect traffic light and stop sign violations. Not honoring a traffic light (i.e., not stopping at a red 30 light) may be one of the most dangerous behavior patterns that a driver can engage in.

Figure 8 illustrates a set of traffic lights at an intersection according to some embodiments of the invention. The Traffic Light Set shown on Figure 8 is labeled as

“Traffic Light Set A” to distinguish it from other possible Traffic Light Sets that may exist at the same intersection. Typically, up to four Traffic Light Sets may exist at an intersection. Also shown on Figure 8 is an “Approaching Traffic Light Set A Notifier”. This Approaching Traffic Light Set A Notifier is strategically located such that vehicles traveling towards Traffic Light Set A will first encounter said Approaching Traffic Light Set A Notifier. After a vehicle has traveled beyond Traffic Light Set A, whether it has continued straight-ahead or has made a turn (left or right) the vehicle will encounter an Interrogator. Only one such Interrogator is shown on Figure 8 (the one that will be encountered should the vehicle decide to continue straight-ahead beyond the Traffic Light Set A). Thus, a Traffic Light Set that is equipped with Traffic Light State Notifiers and/or with a Stolen Vehicles List Notifier, will (from the point of view of an approaching vehicle) be preceded by an Approaching Traffic Light Set Notifier and will be followed by an Interrogator, irrespective of the direction of said vehicle beyond said Traffic Light Set.

15

Figure 8 also illustrates that each individual Traffic Light Assembly (responsible for managing traffic in some specific direction; straight ahead, left, or right) may have associated with it a Traffic Light State Notifier according to some embodiments of the invention. Information from each Traffic Light Assembly is sent (via physical connection or wirelessly) to the corresponding Traffic Light State Notifier. Information may also be transmitted from the one Traffic Light State Notifier designated as the Master, to the other Traffic Light State Notifier(s) that are associated with the same Traffic Light Set and are designated as Slave(s). Information from the Master may also be transmitted to the Stolen Vehicles List Notifier associated with the same Traffic Light Set (also designated as a Slave on Figure 8). In, general, information may flow bi-directionally throughout the chain of Traffic Light Set Notifiers, from any Notifier to any other, as shown on Figure 8. Information may also flow from a Notifier that is associated with a particular Traffic Light Set to at least one Traffic Light Assembly associated with said Traffic Light Set.

As noted earlier, according to some embodiments of the present invention, a vehicle approaching Traffic Light Set A will first encounter the Approaching Traffic Light Set A Notifier. The Approaching Traffic Light Set A Notifier informs the

vehicle that it is about to enter the listening range of a possible plurality of Traffic Light Sets, but it is only to listen and pay attention to transmissions (notifications) originating from Notifiers of Traffic Light Set A. The Approaching Traffic Light Set A Notifier also informs the vehicle of the Transponder listening frequencies 5 corresponding to Traffic Light Set A (chosen so as to maintain orthogonality between the transmissions of the plurality of Notifier sets corresponding to a plurality of Traffic Light Sets that may be proximate at an intersection). The Approaching Traffic Light Set A Notifier transmits its notification periodically (say once every 500 msec) repeating said notification on all Transponder listening frequencies within the 10 repetition interval (within the 500 msec). An illustrative packet format for the Approaching Traffic Light Set Notifier is shown in Figure 9a.

In some embodiments, each Traffic Light State Notifier periodically transmits a notification informing Transponders of its associated Traffic Light Assembly state. 15 The Traffic Light State Notifier receives information regarding the state of its corresponding Traffic Light Assembly, for example, from the corresponding Traffic Light Assembly itself (see Figure 8). As with all Notifiers, the Traffic Light State Notifier will repeat its notification on all Transponder listening frequencies (within a predetermined time interval) so that all vehicle Transponders within listening range 20 can be notified. An illustrative packet format for the Traffic Light State Notifier is shown in Figure 9b. An intercepting Transponder first correlates the information that it has received from the Approaching Traffic Light Set Notifier with the Traffic Light Set ID field in the Traffic Light State Notifier packet. If a match is found, the Transponder copies the Traffic Light Assembly ID, ToD, position coordinates, and traffic light state fields found within the Traffic Light State Notifier packet. The 25 Transponder will keep separate records of traffic light state notifications corresponding to different Traffic Light Assembly IDs. These separate records will be updated in ToD and Traffic Light State as new notifications with correlating Traffic Light Assembly IDs arrive with new parameters in said corresponding ToD and 30 Traffic Light State fields.

Frequency coordination between the Stolen Vehicles List Notifier and the Traffic Light State Notifier(s) associated with a particular Traffic Light Set, such as the Traffic Light Set shown on Figure 8 now will be described according to some

embodiments of the invention. Some embodiments of the invention may avoid collisions between the transmissions of the plurality of Notifiers that may be associated with the plurality of Traffic Light Sets that may be situated at a given intersection. This may be accomplished as follows: At each intersection, each Traffic
5 Light Set (A, B, C, D) may be assigned a different orthogonal subset of frequencies for its corresponding Notifiers to use. Thus, upon notification by the Approaching Traffic Light Set Notifier, a Transponder may select a frequency from said assigned subset of frequencies to listen to while ignoring all other frequencies that may be associated with other proximate Traffic Light Sets. This can guarantee
10 frequency orthogonality between the emissions of a plurality of Notifiers corresponding to a plurality of Traffic Light Sets that may be situated in close proximity at an intersection, and can allow the plurality of Notifiers corresponding to different proximate Traffic light Sets to operate independent of each other, without the need for synchronization, while still avoiding collisions.

15 In accordance with some embodiments of the invention as illustrated in Figure 8, one Traffic Light State Notifier per Traffic Light Set may be designated as a "Master". The Master may transmit its notification pseudo-randomly over the entire designated frequency sub-band while keeping all other Notifiers inhibited. When the Master
20 has delivered its notification over all associated frequencies (thus capturing all proximate Transponders) the Master then sequentially activates the other Traffic Light State Notifiers, designated as Slaves, to deliver their notifications at frequencies that have been pseudo-randomly chosen by the Master. In some embodiments, the Master, besides dictating the hop frequencies of the Slaves, transmits via its
25 notification to the Transponders the frequency to be transmitted by the next-in-line Notifier. Each Slave Notifier via its notification packet also informs the Transponders regarding the frequency to be used by the next-in-line Slave Notifier. Thus, in some embodiments, the Master Notifier is the only Traffic Light Set Notifier that needs to perform "capturing" of Transponders by repeating the
30 notification on all frequencies. The above time-frequency coordination embodiments, besides avoiding collisions between the transmissions of the plurality of Notifiers that may be associated with a given Traffic Light Set, may also "capture" Transponders (following the first "hit" by the Master) so that notifications may be heard, thereafter, by such captured Transponders on first transmission.

In some embodiments, the Interrogators following a Traffic Light Set can be of either type – Independent or Dependent. First, assume that Interrogators of the Independent type follow Traffic Light Sets. If a vehicle travels straight-ahead past a Traffic Light Set, and upon interrogation presents a Red Traffic Light State response (within the Traffic Light Assembly S field; see Figure 3) then that vehicle is identified as having violated the straight-ahead stop light signal. If a vehicle makes a left turn following the Traffic Light Set and upon interrogation presents a Red Traffic Light State response (within the Traffic Light Assembly L field; see Figure 3) then that vehicle is identified as having violated the left-turn stop light signal. If a vehicle makes a right turn following the Traffic Light Set, and there is no specific right turn Traffic Light Assembly (as is quite often the case) the Interrogator will look for either a Green Traffic Light State within the Traffic Light Assembly S field, or a full stop indication and Right Turn Permitted on Red validation¹³. The “Right Turn Permitted on Red” state (either YES or NO) may be provided by either the Traffic Light State Notifier associated with the right-turn Traffic Light Assembly (if present) or by another Traffic Light State Notifier belonging to the same Traffic Light Set.

In accordance with the second embodiments, and in addition to all other embodiments already discussed with respect to said second embodiments, Transponders may be configured such as a non-zero vehicular velocity in conjunction with straight-ahead motion and a Red Traffic Light State from a corresponding (straight-ahead) Traffic Light Assembly will trigger Transponder broadcasts. Transponders may also be configured so that vehicular motion in conjunction with having made a left turn and a Red Traffic Light State from the corresponding left turn Traffic Light Assembly will also trigger Transponder broadcasts, etc...

The notion of having associated a Traffic Light State Notifier with each Traffic Light Assembly (see Figure 8) raises the prospect of adaptive optimal traffic control, according to some embodiments of the invention. In response to the “state” of traffic

¹³ In some embodiments, in establishing the severity of a violation when a turn is involved, the right- or left-turn blinker state may also be examined by the Interrogator. That is, having made a legal left turn but without having indicated your intention to do so, is a small (relatively speaking) violation. However, the driver's profile may be updated, even in response to minor violations, and the driver's

- (i.e., volume and average speed of traffic moving in a certain direction) the CPU may send Traffic Light Assembly control commands to certain select Traffic State Notifiers. As is illustrated on Figure 8, the bi-directional signal path between a Traffic Light State Notifier and the associated Traffic Light Assembly may be used
- 5 to relay the information received by the Traffic Light State Notifier from the CPU to the corresponding Traffic Light Assembly. Said information may change, for example, the time intervals that the Traffic Light Assembly spends on Green and Red. As such, traffic flow may be altered.
- 10 In some embodiments, the CPU may ascertain, in substantially real time, the current traffic state (over a geographic area) from a plurality of Interrogators. In response to the current traffic state, the desired traffic state, and the state of a plurality of Traffic Light Assemblies, the CPU may execute an optimization algorithm (e.g., Kalman-based) to determine the optimum set of parameters for said plurality of Traffic Light
- 15 Assemblies so as to optimally bring about the desired traffic state. Optimal and (nearly) real-time adaptive feedback control of the traffic state may thus be performed by the CPU.

8. THE STOP SIGN NOTIFICATOR

20

In accordance with these embodiments, a Transponder is notified by a Notifier that it is approaching a stop sign (or that it has just passed by a stop sign). As such, the vehicle associated with the notified Transponder is expected to execute (or to have executed) a complete stop at the stop sign. Thus, in response to such a notification,

25 the vehicle's velocity is examined over a time interval ($\pm \tau$) about the notification. If a zero velocity reading is found, the vehicle has obeyed the letter of the Law and has stopped at the stop sign; if not, the vehicle is in violation. If the vehicle has not made a complete stop, other questions such as did the vehicle slow down, and if yes by how much, may be asked.

30

long-term record may thus be established. This type of data may be an input for insurance companies in setting rates for individuals.

9. THE “HHTL” AND THE “HHTR”

The Hand-Held Transponder Loader (HHTL) and the Hand-Held Transponder Retriever (HHTR) are devices that input and output, respectively, information to/from the Transponder according to some embodiments of the present invention. The exchange of information between a HHTL and a Transponder or a HHTR and a Transponder preferably takes place wirelessly. The HHTL may be, for example, used by an Inspection Station to update the contents of a particular Transponder following an inspection of the vehicle associated with said Transponder. The HHTL may also be used to load into a Transponder a plurality of images, each reflecting characteristics of an authorized driver, so that in the event of a violation, correlations between the driver's “image” and the a priori stored images may be performed locally (within the Transponder). These embodiments can reduce or minimize the amount of data that would need to be relayed to the CPU. The HHTL may also be used by the Motor Vehicles Department to periodically load data into Transponders.

In some embodiments, the HHTR may be a portable device that may be used to (wirelessly) extract the records of drivers from Transponders. Law enforcement officials and insurance company agents, for example, may be users of HHTRs. The HHTR may also be equipped with means to delete Transponder records in response to specific input instruction.

10. OTHER EMBODIMENTS

25 10.1 Ensembles Of Shipping Containers/Transportable Vehicles

According to other embodiments of the invention, shipping containers, or any other ensemble of transportable vehicles, may be equipped with Transponders. Each Transponder may be configured to accept inputs from one or more sensors of a container/transportable vehicle unit, relating to, for example, the contents of the container/transportable vehicle unit, its environmental state, whether the unit has been opened (and when) since it left a particular origin, etc..., and may keep a record of such sensory inputs. At a particular destination (a loading/unloading dock) an

Interrogator may be used to survey the ensemble of such container/transportable vehicle units.

In order to conserve battery life (if the Transponder of a container/transportable vehicle unit is operating on battery power) the Transponder may be configured to have a sleep mode whereby it may, for example, sleep for 1 sec., and then wake-up to listen and take sensor readings for 10 msec. If during the listening interval the Transponder detects a “presence signal” of an Interrogator, the Transponder may remain awake in order to read the interrogation message content and respond with unique identifying information. The Transponder may also relay to the Interrogator the contents of its record (a measure of its sensory inputs). Following the Transponder’s response to the interrogation, and following a confirmation of reception sent to the Transponder by the Interrogator, the Transponder may return to its sleep mode cycle (i.e., sleeping for 1 sec. and awaking-up for 10 msec. to listen and take sensor readings). Any subsequent detections of the Interrogator’s presence signal by the Transponder may be ignored by a Transponder that has already responded and has received confirmation that its response has been received. The time interval for which the subsequent detections of the Interrogator’s presence signal may be ignored (by a Transponder that has responded and has received confirmation) may be *a priori* determined and stored within the Transponder, may be chosen by the Transponder, or may be dictated by the Interrogator’s interrogation message. The Interrogator’s presence signal may be a direct-sequence-spread and/or frequency-hopping waveform (or even a simple CW) whose parameter values are *a priori* known to the Transponder. Thus, each time the Transponder wakes-up, acquisition of the Interrogator’s presence signal is attempted. If the presence signal is acquired, the Transponder remains awake in order to receive and process an Interrogation.

To reduce or minimize the probability of Transponder response collisions (particularly in areas where there may be a large ensemble of container/transportable vehicle units equipped with Transponders) the Interrogator may selectively command (via the interrogation message) a subset of the ensemble of container/transportable vehicle unit Transponders to respond. Thus, sequentially, subset-by-subset, the entire ensemble of Transponders may be interrogated to respond.

An ensemble of container/transportable vehicle units that may be en-route (on a barge, railroad cart, airplane, or a truck) may also be subject to the same interrogation process described above. In this case, however, a special purpose Interrogator device may be used. The special purpose Interrogator device may be permanently installed
5 on the barge, railroad cart, airplane, or truck. The special purpose Interrogator device may contain an Interrogator (as specified above) in conjunction with a Transponder. The Interrogator component of the special purpose Interrogator device may be configured to interrogate the ensemble of container/transportable vehicle units, as described earlier, and thus gather a summary of their state. This summary may then
10 be relayed to the Transponder component of the special purpose Interrogator device. Thus, as the barge, railroad cart, airplane, or truck that is transporting the ensemble of container/transportable vehicle units passes by an Interrogator (of the type that has been described for usage on the side of roads and/or highways) information reflecting the state of the container/transportable vehicle units ensemble that is en-route may be
15 relayed to a CVIS CPU. The ability to interrogate and ascertain the state of the container/transportable vehicle units ensemble, as it travels from a point of origin to a point of destination, may offer significant Home Land Security benefits.

10.2 Activation/de-activation of CVIS

In some embodiments of the invention, every vehicle may be CVIS equipped (may have a built-in Transponder). However, in other embodiments, not every vehicle's Transponder may be activated. A vehicle's Transponder may be activated voluntarily by the owner of the vehicle or, in the event that it isn't, a vehicle's
25 Transponder may be activated by a Government authority. For example, an automobile insurance company may offer an insurance premium discount with CVIS activation of a vehicle. Thus, some people may choose to have their vehicles CVIS activated. A vehicle that is not CVIS activated and is involved in a number of accidents/traffic violations, may be ordered by the authorities to become CVIS activated.
30

CVIS may be activated in a vehicle in response to an interrogation message. In some embodiments, the Transponder of a vehicle that is not CVIS activated continues to receive interrogations, it simply does not respond. As such, the vehicle's Transponder

may receive an interrogation specifying the vehicle's unique ID and ordering the vehicle to become CVIS active. Thus, from that time on, the Transponder of the vehicle will configure itself in a CVIS active mode and will begin responding to interrogations. This covert mode of CVIS activation may be used by the authorities

5 where there is probable cause (as is the case with legal wire-tapping) to gather information on suspect behavior. A vehicle that has been CVIS activated by the above technique may become CVIS de-activated in response to an interrogation ordering the vehicle's Transponder back into a CVIS dormant mode.

10 **10.3 Anti-Spoofing Embodiments Of CVIS**

A jamming device may be used in the vicinity of a CVIS Transponder to prevent the Transponder from deciphering interrogations and/or notifications and thus prevent the Transponder from ever responding to interrogations. The jamming device may be

15 configured to jam the entire band over which the Transponder is configured to receive information from Interrogators and/or Notifiers. In order to defeat this threat, the following embodiment may be used:

Since a Transponder knows the frequency that its receiver is tuned to, the

20 Transponder's transmitter may be tuned to the same frequency to transmit an *a priori* known (to the Transponder receiver) message. In this mode, the transmitter of the Transponder may use a radiating element that is sufficiently apart (spatially) from the Transponder's receiving antenna element (one antenna element may be situated near the front of the vehicle while the other may be positioned near the rear of the vehicle).

25 If the *a priori* known message that is transmitted by the Transponder's transmitter is not received reliably by the Transponder's receiver (while all other Transponder diagnostics are showing no malfunction) a warning signal/message/alarm may instruct the vehicle's operator to disable the jamming device. If the effect of the jamming device persists for more than a predetermined time interval (following the warning

30 signal/message/alarm) then the vehicle's engine may, for example, stop.

In other embodiments, given the relatively low-cost nature of the Transponder, large-scale redundancy may be provided. Each vehicle may contain a plurality of Transponders, all networked together wirelessly (or otherwise) so that if one fails, the

next can provide the necessary functions. The plurality of Transponder chip-sets may be situated in different areas of a vehicle so as to make it difficult to identify and disable. Transponder chip-sets may also be integrated with other electronic functions of a vehicle such that the Transponder assumes an amorphous (or distributed) nature, 5 thus making it difficult for someone to identify, isolate, and disable, without also causing harm to other vehicular electronics.

10.4 Integration Of GPS Signal-Processing & Satellite/Terrestrial Transceiver Units With The CVIS Transponder

10

A vehicle may be equipped with GPS signal processing means and with a satellite/terrestrial transceiver capable of communicating directly with a CVIS CPU. Thus, a vehicle may attain a measure of its position from GPS signal processing. Furthermore, a vehicle may be interrogated via a terrestrial wireless system (cellular, 15 PCS, or other) or via a satellite system. In response to such an interrogation, the vehicle may ascertain a measure of its position from processing of GPS signals and may relay directly to a CPU, via the satellite/terrestrial transceiver unit, information responsive to the interrogation.

20 10.5 Use of CVIS by Emergency Vehicles to Control Traffic Signals

Fire trucks, Police vehicles, ambulances, and other authorized vehicles may be equipped with Transponders capable of controlling the traffic signals at intersections along their path. A Transponder of an authorized vehicle may receive, from an 25 Approaching Traffic Light Set Notifier, information regarding an approaching Traffic Light Set. The Transponder of the authorized vehicle may then use this information to command the Traffic Light Set in its path to turn green while all other Traffic Light Sets that may exist at the same intersection are commanded to turn red. This embodiment of CVIS may provide significant additional safety to motorists, 30 passengers of vehicles, and pedestrians that may be in the vicinity of an emergency vehicle while the emergency vehicle is pursuing its objective at high speed. A hearing impaired person, for example, who may not hear the sirens of an approaching emergency vehicle, may respond to the altered state of traffic signals. Similarly, a vehicle packed with teenagers, with their stereo blasting away at maximum setting,

may not hear the sirens of an approaching emergency vehicle but may respond to the altered state of traffic signals.

- In the drawings and specification, there have been disclosed typical preferred
- 5 embodiments of the invention and, although specific terms are employed, they are used in a generic and descriptive sense only and not for purposes of limitation. The following claim is provided to ensure that the present application meets all statutory requirements as a priority application in all jurisdictions and shall not be construed as setting forth the full scope of the present invention.
